SOLAR-ASSISTED COMPUTE FOR SMALL AI LABS

Intelligence powered by sunlight.

An accelerator workstation, a solar array and storage, sized and scheduled together, so small labs can adapt and run their own models on energy they can see.

Small AI labs are held back by access, not talent.

Two in three AI builders have no GPU of their own. The cost shows up as delayed and abandoned work, not as a line on an invoice.

EXHIBIT 1

Delay and access top the list of what blocks small labs

Share of respondents, % (n = 600)

14.7 h

Median wait for a compute job

Queues and quotas hold work back, even where cloud credit exists.

3 h

Lost to power outages each week

The median respondent has grid power 22 hours a day.

SOURCE: OUR SURVEY OF 600 AI PRACTITIONERS IN 42 COUNTRIES, 2026

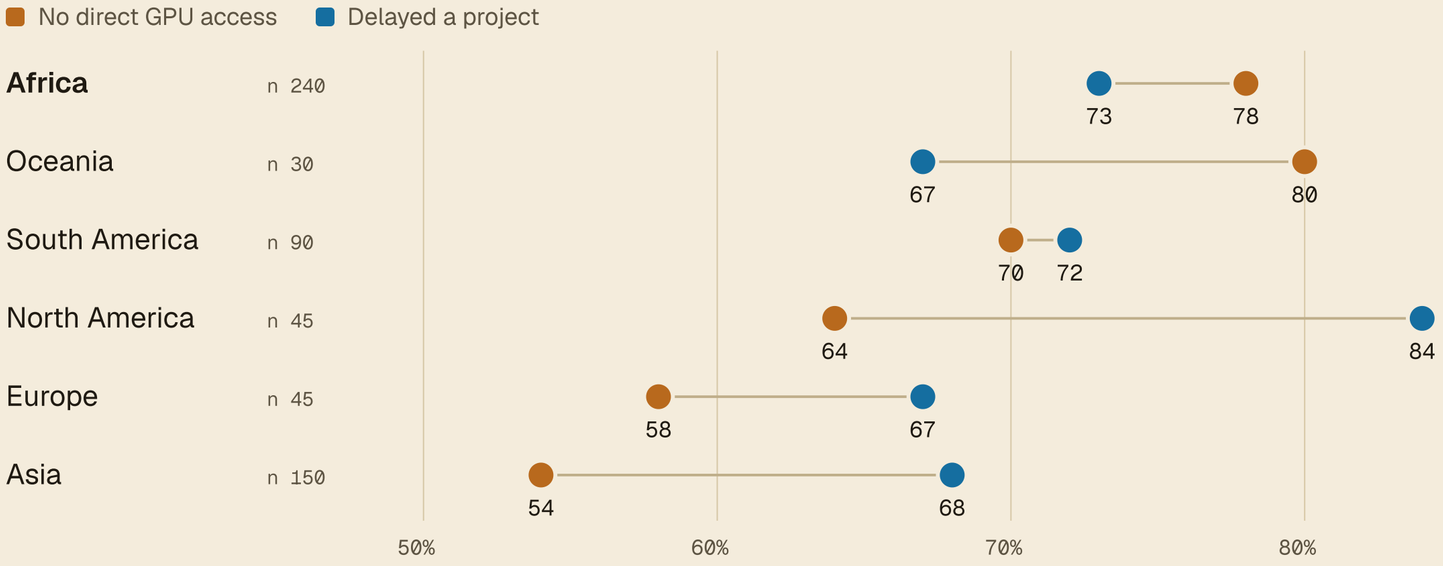

The gap is widest in Africa, where we start.

Our first customer is an independent builder or small applied research team adapting open-weight models, with a defined task and a sunny site.

EXHIBIT 2

Africa pairs the most respondents with the least GPU access

Share of respondents by region, %

240

Respondents in Africa, the largest group

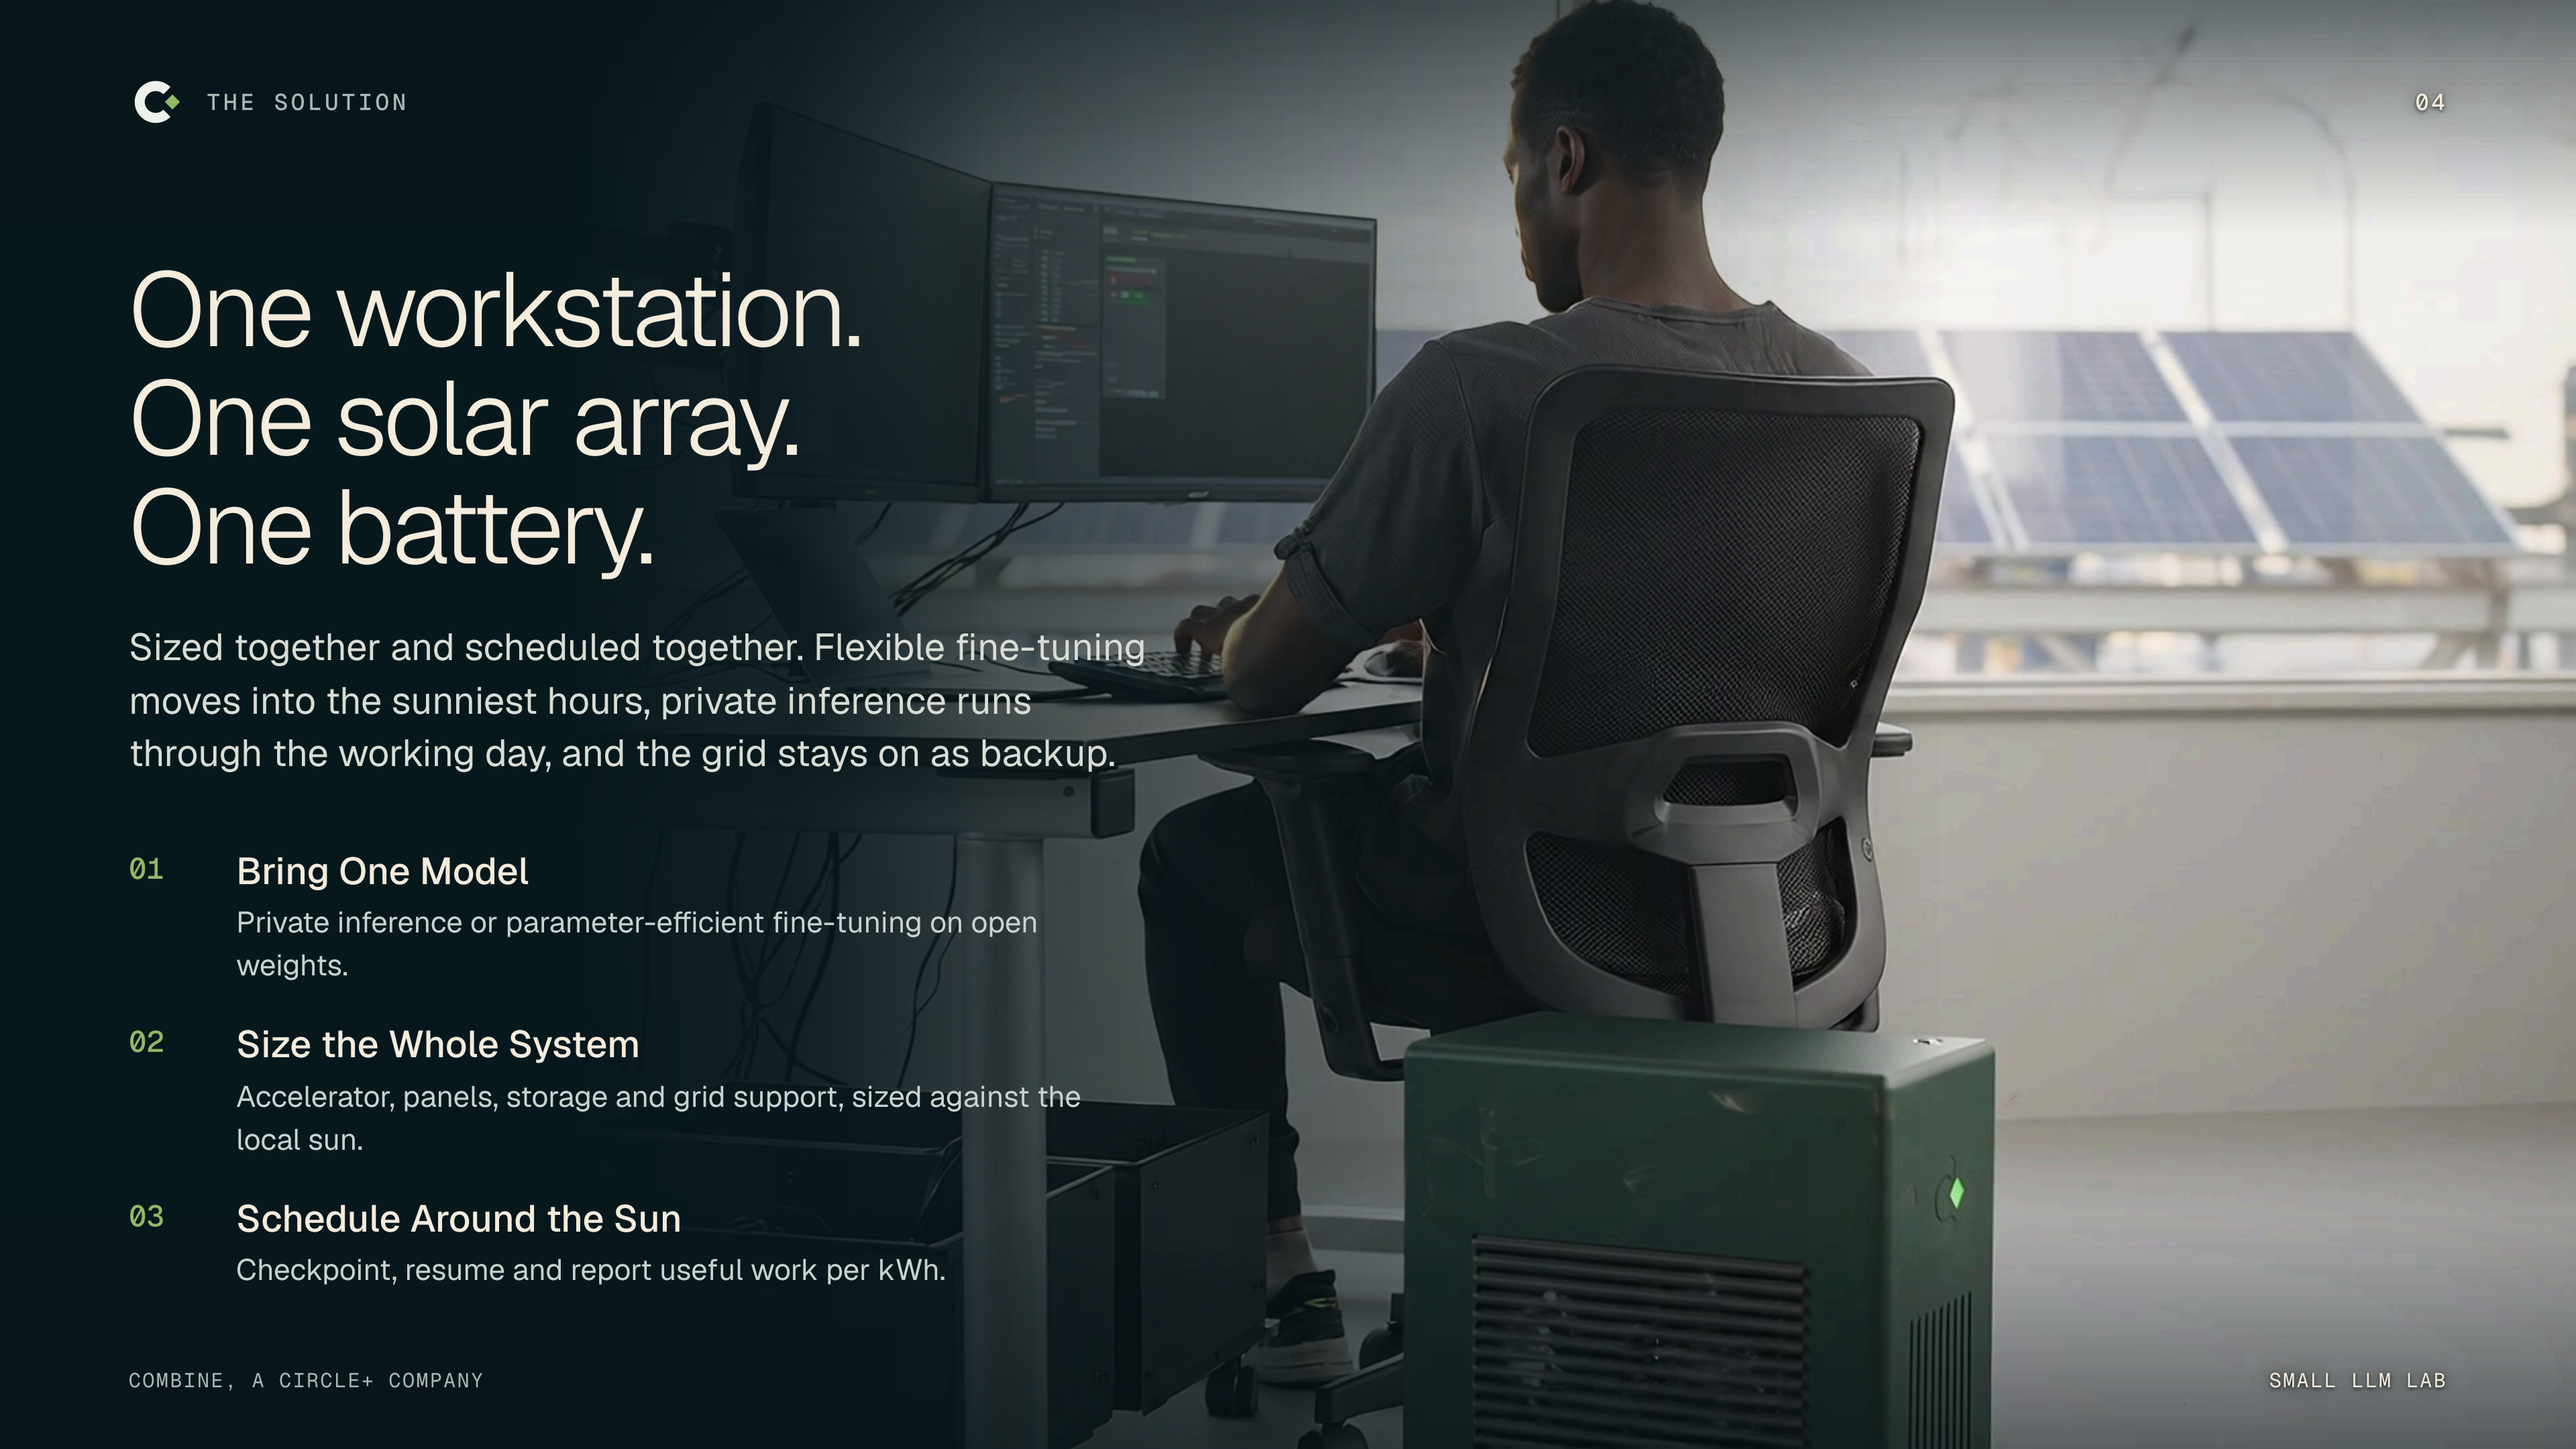

78% have no direct GPU and wait a median 15.8 hours for a job.

39%

Do LoRA or QLoRA fine-tuning

Their work is adaptation and local inference on Llama, Mistral, Gemma and Qwen, a fit for one workstation.

SOURCE: COMBINE SURVEY OF 600 AI PRACTITIONERS IN 42 COUNTRIES, 1 FEBRUARY TO 1 OCTOBER 2026. OCEANIA HAS 30 RESPONDENTS

One workstation. One solar array. One battery.

Sized together and scheduled together. Flexible fine-tuning moves into the sunniest hours, private inference runs through the working day, and the grid stays on as backup.

01 **Bring One Model**

Private inference or parameter-efficient fine-tuning on open weights.

02 **Size the Whole System**

Accelerator, panels, storage and grid support, sized against the local sun.

03 **Schedule Around the Sun**

Checkpoint, resume and report useful work per kWh.

The node. Three parts, one system.

About 2 kWp of panels, 5 to 15 kWh of storage and one accelerator workstation, in very dark forest-green anodised aluminium.

01 Workstation

One 600 W class accelerator for parameter-efficient fine-tuning and private local inference.

Heavy jobs run in the sunniest hours. Inference runs all day.

02 Storage & Inverter

5 to 15 kWh of usable lithium storage, grid support for shortfalls, checkpointing so no run is lost.

Carries the lab through cloud and evening, with the grid as backup.

03 Outdoor PV

Four 500 W panels on a fixed rack, tilted 10° to self-clean in rain, sized from two satellite records.

Sized to the local sun before anything ships.

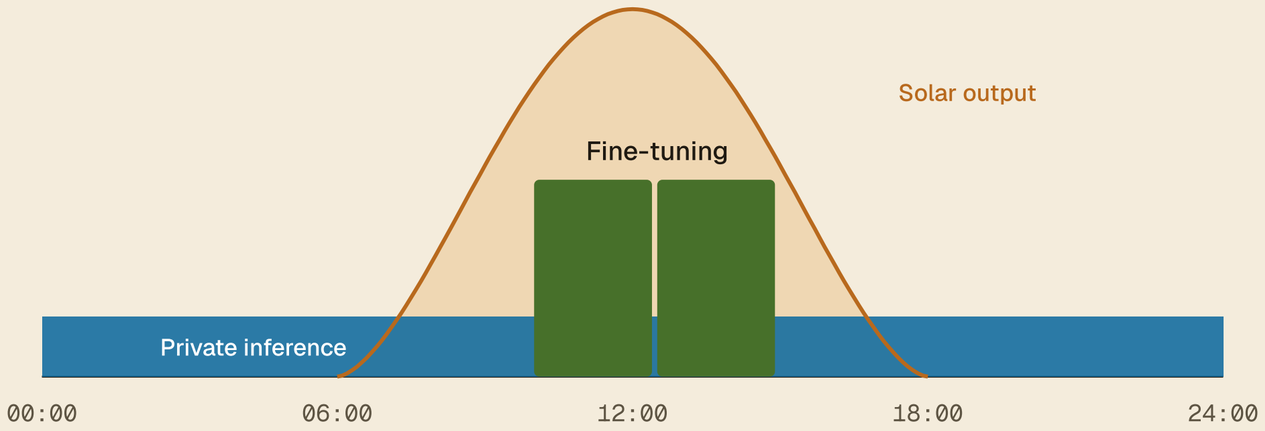

The heaviest work runs in the brightest hours.

Our scheduler knows the sun before the lab does. Fine-tuning queues for the solar peak, inference runs through the day, and every run checkpoints so a cloud never costs a job.

EXHIBIT 3

A day on one node

Solar output and scheduled work across 24 hours

~97%

Of a year's load from the sun MODELLED

A 2 kWp array and 5 kWh of storage on a typical sunny site.

62%

Less grid import MODELLED

From sun-aware scheduling alone, in the tightest case.

Software that ships with every node

Energy-aware scheduling, checkpoint and resume, device health, and a report of useful work per kWh.

One idea, three scales.

The lab is the first product. The same sizing and scheduling carries to a logistics yard and a data center campus.

01 Small LLM Lab

One workstation, one array, one battery. Fine-tune and run private models on hardware the lab controls.

02 Bay Yard

A pole-mounted camera node with its own panel and battery reads bay status on a small vision model.

03 Data Center

Accelerator racks beside a solar field, storage and a utility connection, with firm power carrying nights.

Start with small labs. Grow into the grid's edge.

Our beachhead is small labs that need local control and have sun to spare, starting in Africa. The same node and software carry to yards and campuses.

01 **Small LLM Labs**

Independent builders and applied research teams adapting open-weight models. Our first customer.

02 **Yards and Edge Sites**

Solar-powered vision nodes for logistics yards, off the grid entirely.

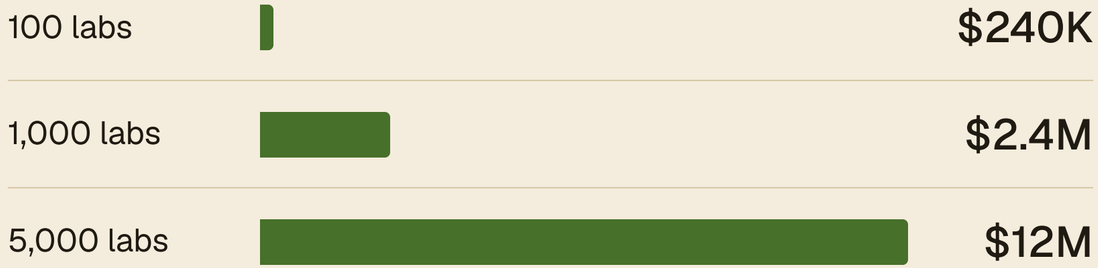

03 **Solar-Assisted Data Centers**

Accelerator racks beside a solar field and storage, with firm power for nights.

EXHIBIT 4

Software revenue scales with the number of labs

Annual recurring software revenue at $200 per lab per month, US$

Deployment and integration revenue comes on top.

Paid evaluation first. Recurring software after.

We sell to the lab lead or technical founder who owns the workload, the budget and the installation decision.

DEPLOYMENT

$1,000 to $3,000

Integration fee per lab for a scoped evaluation or installation. Hardware and electrical work quoted separately.

RECURRING SOFTWARE

$200 per lab per month

Energy-aware scheduling, device health and reporting of useful work per kWh.

01 Discovery

Qualify the model, site and budget, starting with the 131 labs that offered to host a pilot.

02 Paid Evaluation

A four-week test against the lab's current setup, with whole-workstation power measured.

03 Repeat Deployment

Turn each pilot into a standard scope, a subscription and a referral. Sales cycle of 1 to 3 months.

The benchmark is the lab's best alternative.

Only Combine brings compute, power and scheduling together on the customer's own site.

BUYER DECISION	Cloud GPU Rental	Self-Built Workstation	System Integrator	
Location and control	Provider infrastructure	Customer site	Customer site	Customer site
Initial investment	Rent capacity	Buy hardware	Hardware and service	Hardware and integration
Power	Provider operates it	Customer designs it	Depends on scope	Solar, storage and grid, sized as one
Workload scheduling	Provider and user tools	User-managed	Depends on scope	Energy-aware, around the sun
Main trade-off	Recurring cost, data leaves the site	Engineering effort	Service dependence	Needs a site with sun

Defensibility: repeatable integrations, operating data from every node, and a workflow labs live in every day.

CLOUD EXAMPLE: AWS EC2 G5. CONFIGURATIONS VARY BY PROVIDER

A pilot pipeline before the first node ships.

131

Labs in the pilot pipeline

Teams that offered a site and a workload to host a pilot.

$125K

Raised by the parent

At a $3M valuation. Circle Plus Africa Inc., incorporated 12 December 2022.

NVIDIA

Inception member

Accepted into the NVIDIA Inception program.

Synopsys

Partnership in progress

For the design flow behind our energy management block.

ROADMAP

DONE

Product Design

Node, hardware and software designed for one lab.

DONE

Sizing Engine

Energy model and Solar Atlas live at combinelabs.tech.

DECEMBER 2026

First Node

Built and power-measured on real fine-tuning runs.

MONTH 6

3 Pilots

Supervised installs with pipeline labs.

MONTH 12

10 Paying Labs

Subscriptions live, standard install scope.

MONTH 24

Repeat Installs

Renewals, referrals and the first yard sites.

Built on NVIDIA. Headed for silicon.

NVIDIA Inception

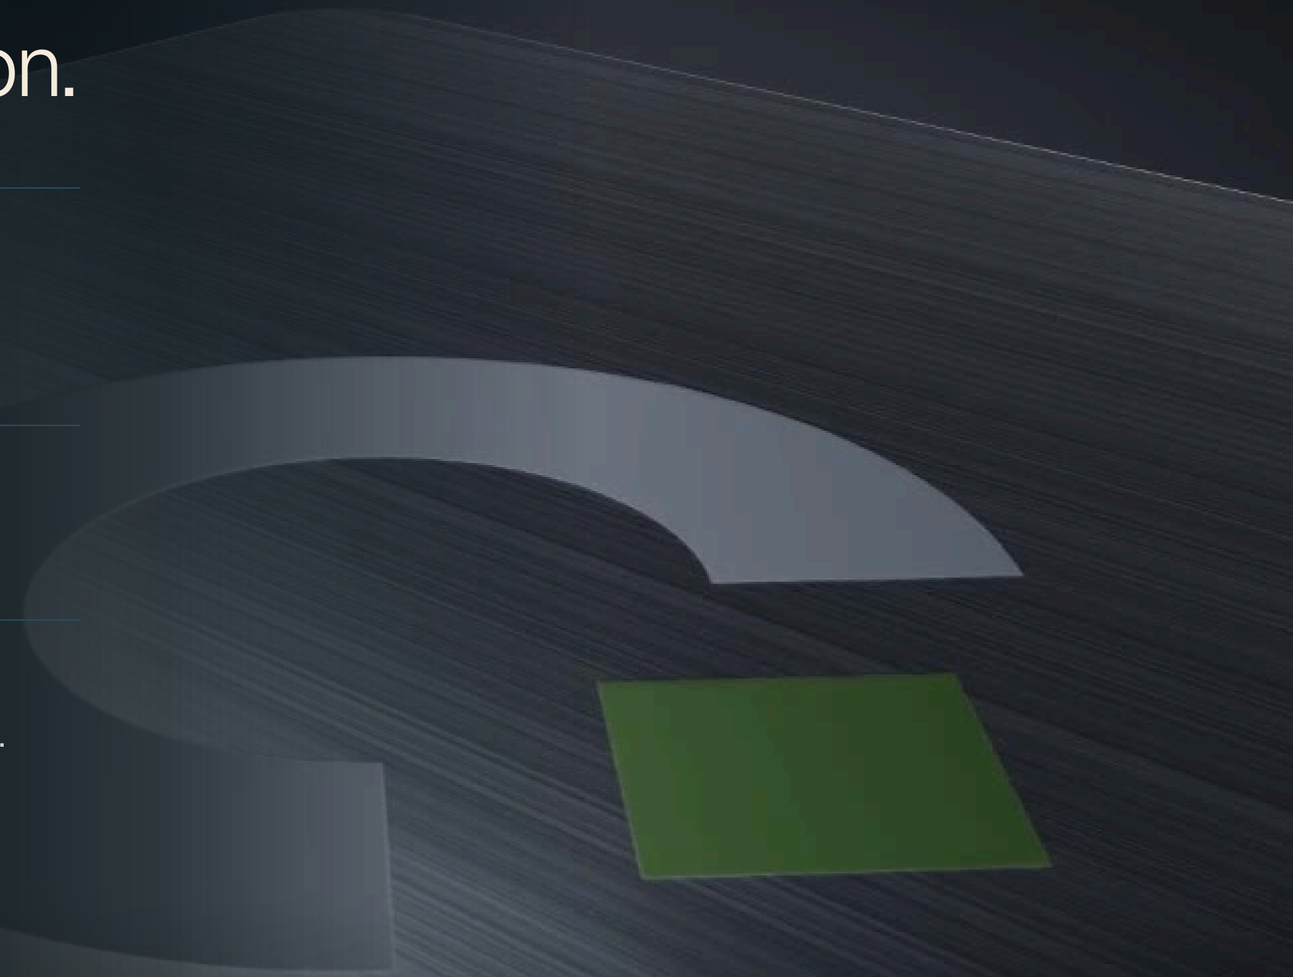

Accelerated local inference and parameter-efficient fine-tuning on an NVIDIA accelerator matched to model size, with CUDA tooling and TensorRT LLM.

Synopsys

A partnership in progress for the EDA flow behind our energy management block.

Inside the Chip

A proposed energy management and scheduling block, explored in simulation only. Silicon follows measured workloads and a written feasibility gate.

CHIP IMAGE: CONCEPT RENDER OF A PROPOSED DESIGN

Founder-led, with hardware and energy depth.

Brian Simiyu

FOUNDER & CEO

Third-time technical founder and Techstars SF alumnus. His previous startup reached $10K MRR on a lean team.

Angel investor and former financial consultant, with a background in data analysis.

Natalie Mutunga

CHIEF HARDWARE ENGINEER

MSc in Energy & Economic Finance, University of Aberdeen.

Leads the node hardware: the workstation, storage and inverter, and the solar array.

techstars_ Microsoft For Startups aws startups NVIDIA INCEPTION PROGRAM 1495 UNIVERSITY OF ABERDEEN

Raising $5M pre-seed.

Previously raised $125K at a $3M valuation. Seeking investor introductions now.

24 months

Runway

$4.5M operating at about $187,500 a month, plus $500K contingency.

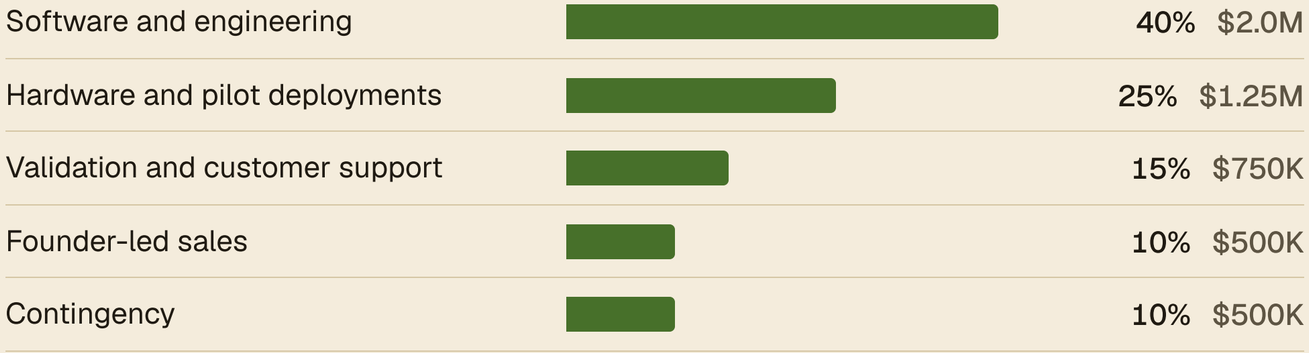

FUNDED MILESTONES

Month 6	Baseline measured, 3 supervised pilots
Month 12	10 paying labs
Month 24	Repeat installs and renewal data

EXHIBIT 5

Use of funds

Share of the $5M round, % and US$

Intelligence powered by sunlight.

Solar-assisted compute for small AI labs. Raising $5M pre-seed to put the first nodes in the field.
